

Why Avro API is the best choice?

Adrian Strugala

March 27, 2020

1 Introduction

Hi! I am a software developer working in C# .NET environment. I'm focused mostly on the backend side of the applications. That means I am delivering the data. Fetching the data. Synchronizing the data. Downloading the data. Checking data quality. Pulling the data. Mixing together data from various sources to produce new data. I think you know what I am talking about.

Fortunately, I am living in a microservice world. The data is well organized. The flag project of my company is build of 40-50 services. Each of them exposes from 5 up to 100 API endpoints. Even my side project is build of 6 services, 20 endpoints in total. I am using 3rd party APIs, public APIs, and open APIs. I mean - I know how to communicate between microservices. I do this every day.

Believe me or not, services love to talk to each other. They do this without any break. All the time. That's good. My customers are able to see the data, manipulate it and delete it. Background jobs are generating reports, documents and whatever they want. The problem starts, when the communication slows down the services and they are not able to play their role correctly.

2 The problem

Some time ago developers in my company were kindly asked to try to not call on-premise microservices more than it's needed. Surprisingly problem was the local internet bandwidth throughput. Funny or not, the solution from management was really to reduce traffic between microservices.

A few days later I heard a conversation between my colleague and his product owner. The PO asked If there is any quick-win on how to improve response time of his service. It wasn't that bad - just a little bit to slow for the users. The colleague started to explain what's the root cause of the problem: his service was fetching data from one API, then another, then 3rd one, authorizing and validating in the meantime. That means service A response time was strongly dependent on services B, C, D, and E. Then colleague as a great professionalist started to enumerate possible solutions: cache part of the data, go in the direction of CQRS and Event Sourcing - start pre- generating view models as soon

as the data changes. His answers were right. But caching in live-APIs is sometimes impossible. Implementation of Event Sourcing is very, very expensive in the existing environment.

I thought about those problems and I found out one, really simple solution which brought 3 main benefits:

- Decrease the microservices communication time
- Reduce the network traffic
- Increase security between microservices

First things first, though. I'll start with a few words about why we are all in love with Json.

3 Why Json is amazing

That's simple - just try to imagine communication without Json. What would you miss the most? The clear and easily readable format? Consistent data model? Maybe the number of tools you can use to parse, read or edit Jsons and even generate it automatically from C# models?

If fact Json has only one disadvantage that comes to my mind - every response and request is sent as plain text. Sometimes it's not a big deal, but in other cases response time of not compressed nor encoded Json API could be a real problem.

4 Why Avro is better

Avro file is build of few pieces:

1. Magic number
2. Chosen codec (null in example)
3. Schema of the data written in Json format
4. The data itself compressed to binary representation

An example of exactly the same data:

Json:

```
1  [  
2      {  
3          "minPosition": 188,  
4          "hasMoreItems": true,  
5          "itemsHtml": "items_html6e64c2b9-dc87-  
6              4be3-b8ba-eca0da96ce78",  
          "newLatentCount": 85,
```

happens, that someone spots the data that shouldn't be read by unauthorized person. Keeping data encoded increases security of the solution. Reading Avro is not a big problem for motivated person, but reduces probability of accidental data leaks.

In a real world case API responses are usually a little bit more complex than in this example. How beneficial is serialization using Avro in comparison to Json? 2 times for this example. 3 times for simple API responses. I was able to reach 50 times using right codec for nested model structures containing huge amount of data.

5 My benchmark results

Enough talking, lets now focus on numbers. Screen below shows data compressed with different formats and encoding. Take carefull look at the sizes. Json file, which size is about 10 000 KB was compressed to Avro file occupying about 2 500 KB (that's 4 times smaller).

One of the greates features of Avro format is possiblity to choose codec type (compression algorithm in fact) used for serialization of the data. In this examples GZip and Deflate encodings are clear winners. Enabling one of them decreases file size to only 200 KB - this means: 50 time less than Json.

10mega.json	25.03.2020 11:30	JSON File	9 945 KB
10mega.avro	20.03.2020 13:59	AVRO File	2 436 KB
10mega.snappy.avro	25.03.2020 11:30	AVRO File	421 KB
10mega.GZip.avro	25.03.2020 11:30	AVRO File	206 KB
10mega.deflate.avro	25.03.2020 11:30	AVRO File	206 KB

Figure 1: Comparison of the same file compressed with different options

At this point let me introduce library that I've created in purpose of handling serializaiton and deserialization C# objects to Avro format: AvroConvert: Github page. I've strongly focused on dev workflow and usability of the package. It's interface should be clear and familiar for every user.

Bechmark below mimics sending API response. Calculates time of serialization of the messege, time for used for transport (based on size) and time of deserialization:

Winner in this category is official implemetation of Avro format in the C# world: Apache.Avro. Unfortunetaly it doesn't support many of key types like: decimal, dictionary, list or Guid.

```

The Benchmark compares Newtonsoft.Json, Apache.Avro, AvroConvert (nuget version) and AvroConvert local version
Number of runs: 10
Progress: 1/10
Progress: 2/10
Progress: 3/10
Progress: 4/10
Progress: 5/10
Progress: 6/10
Progress: 7/10
Progress: 8/10
Progress: 9/10
Progress: 10/10

Json:           Serialize: 137 ms 11130 kB; Deserialize: 193 ms
Apache.Avro:    Serialize: 163 ms 6283 KB; Deserialize: 211 ms
Avro Headless:  Serialize: 117 ms 6283 KB; Deserialize: 261 ms
Avro Deflate:   Serialize: 349 ms 3080 KB; Deserialize: 305 ms
Avro vNext:     Serialize: 106 ms 6283 KB; Deserialize: 243 ms

Summarize:
Let's produce one value for each of the records. Assume internet speed 100mb/s and calculate how fast the data is send between to microservices:

Json:           1200,203857421875 ms
Apache.Avro:    864,9125518798828 ms
Avro Headless:  860,9128570556641 ms
Avro Deflate:   894,6291961669922 ms
Avro vNext:     839,9128570556641 ms

```
